Project title : Audio Emailer

Description

Individuals can find it difficult to catch up on emails. It is estimated that the average worker spends more than 11 hrs/week on emails. This increases with senior executives and very busy individuals and as such, they miss important emails and deadlines, hire an executive assistant or look for other creative ways to fix this problem.

AudioEmailer is an application that attempts to fix this problem by converting a user's email into speech. The application should work as a regular email client that allows users to read and send emails but in addition, the application should be able to read the emails to the user, using a chosen voice.

The application can be developed as a desktop or web (optionally for mobile) application.

Out of scope

The focus of the application is on AudioEmailer reading the email to the user and not for the user to send voice messages or converting the user's voice to text - see also feature 13

Application users

Expected to be busy executives (professionals), students or visually impaired individuals, eTourism (company) staff

Expected Features

1. act as an email client, where users can send and receive emails
2. provide a 'local' user login using a (test) Google account (email + password). You must setup a new account for the team; do not use your own/university gmail
3. access at least two types of remote email servers; one will be the same Google gmail (used to login) and at least one other email server type, e.g. hotmail/yahoo. You will at least use IMAP and SMTP protocol and better solutions will access more protocol/s; ensure you identify these in your final report
4. allow a user to select which email/s to read out
5. allow a user to request all unread emails to be read out
6. read out the title (only) of any attachment/s
7. allow a user to select specific times when emails should be read. e.g. Read all unread emails to me by 5pm
8. securely keep email access details between sessions, i.e. persist details securely in a database and retrieve when the user next logs in
9. allow a user to logout
10. allow configuring preferences (persisted) for
    a. a preferred voice from a list of 3+ choices
    b. a preferred reading speed
    c. different interface themes, e.g. light/dark mode
    d. whether/how long to pause at the end of each paragraph/sentence; *it should be possible to have the whole of an email read out reliably in one go*
11. provide a suitable interface including secure login; this is expected to be a GUI
12. Optionally allow users to mark (star) important emails
13. Optionally provide a suitable speech driven interface
